Restriction factors, such as the retroviral complementary DNA deaminase APOBEC3G, are cellular proteins that dominantly block virus replication^{1–3}. The AIDS virus, human immunodeficiency virus type 1 (HIV-1), produces the accessory factor Vif, which counteracts the host's antiviral defence by hijacking a ubiquitin ligase complex, containing CUL5, ELOC, ELOB and a RING-box protein, and targeting APOBEC3G for degradation^{4–10}. Here we reveal, using an affinity tag/purification mass spectrometry approach, that Vif additionally recruits the transcription cofactor CBF- β to this ubiquitin ligase complex. CBF- β , which normally functions in concert with RUNX DNA binding proteins, allows the reconstitution of a recombinant six-protein assembly that elicits specific polyubiquitination activity with APOBEC3G, but not the related deaminase APOBEC3A. Using RNA knockdown and genetic complementation studies, we also demonstrate that CBF- β is required for Vif-mediated degradation of APOBEC3G and therefore for preserving HIV-1 infectivity. Finally, simian immunodeficiency virus (SIV) Vif also binds to and requires CBF- β to degrade rhesus macaque APOBEC3G, indicating functional conservation. Methods of disrupting the CBF- β -Vif interaction might enable HIV-1 restriction and provide a supplement to current antiviral therapies that primarily target viral proteins.

Mammals have evolved cellular proteins termed restriction factors that function to prevent the spread of mobile genetic elements including retroviruses^{1–3}. As a counter-defence, most retroviruses, including the human pathogen HIV-1, have developed mechanisms to prevent restriction, often through subversion of the host's ubiquitin–proteasome system. In eukaryotic cells, 8.6-kDa ubiquitin moieties are added to a target protein by sequential action of one of two ubiquitin-activating enzymes (E1), which transfer ubiquitin to a pool of dozens of ubiquitin-conjugating enzymes (E2) that, in turn, collaborate with hundreds of ubiquitin ligases (E3) to catalyse transfer to specific substrates¹¹. If more than four ubiquitins are joined together through K48 linkages, the target protein is usually degraded by the 26S proteasome¹². At least three HIV-1 proteins, Vif, Vpu and Vpr, hijack cullin-RING E3 ligases consisting of CUL5, CUL1 and CUL4A to promote ubiquitination and degradation of APOBEC3 family members (for example, APOBEC3G, A3G), BST2/ tetherin and an unknown, putative restriction factor, respectively². Understanding the composition of cullin-RING E3 ligase complexes and the underlying cellular signalling components may provide therapeutic routes for treating a variety of human diseases, including infection by HIV-1.

HIV-1 Vif is recruited to CUL5 by virtue of its SOCS box, which contains an elongin C binding helix (the BC-box), a conserved HCCH Zn binding motif and a short Cullin Box^{4–6}. Although a structure of the BC-box peptide in complex with the heterodimer of Elongin B and C

(ELOBC) has been reported¹³, the architecture of the full-length Vif in complex with host factors has remained elusive, in part because Vif complexes have poor solubility and activity. We therefore reasoned that Vif may bind an additional host factor and that such a factor may render it more tractable *in vitro*.

We took an unbiased proteomic approach to identify host factors that bind all 18 HIV processed and polyproteins using an affinity tag/purification mass spectrometry (AP-MS) approach^{14,15}. To this end, 2 \times Strep and 3 \times Flag was fused to the carboxy (C) terminus of these factors, including Vif. The tagged Vif construct was both transiently transfected into HEK293 cells and used to make a stable, tetracycline-inducible Vif-Strep-Flag Jurkat T cell line (Fig. 1a). Epitope-tagged Vif was purified from both cell types using antibodies specific to either Strep or Flag and aliquots of the co-purifying proteins were subjected to SDS-polyacrylamide gel electrophoresis (SDS-PAGE) (Fig. 1b). Materials from each step were analysed by mass spectrometry¹⁴.

Using a new scoring system for data derived from AP-MS studies, termed Mass Spectrometry Interaction Statistics (MiST)¹⁵, we identified 24 Vif-human protein-protein interactions with seven of them found in both cell types (Fig. 1c). Seventeen of these were verified independently by co-immunoprecipitation (Supplementary Fig. 1). Among these were the components of the E3 ubiquitin ligase complex, CUL5, ELOB and ELOC, known to interact with Vif and trigger A3G degradation^{4,6,8–10}. Although the RING-box protein RBX1 was originally reported as part of this complex⁴, only RBX2 was above the MiST score threshold used¹⁵ consistent with recent work showing that it binds CUL5 (refs 16, 17). We did not find endogenous A3G, probably because of its poor expression in HEK293 and Jurkat cell lines exacerbated by further depletion through Vif-mediated degradation. We did find Vif associating with two proteins that function in autophagy, AMRA1 and SQSTM, as well as with the transcriptional co-repressor complex NCOR1/HDAC3/GPS2/TBL1R (the last only in T cells) (Fig. 1c). Also, in both cell types, Vif was found to interact with the transcription cofactor CBF- β , which is known to heterodimerize with the RUNX family of transcription factors¹⁸.

To determine if any of the newly defined Vif interactors belong to the Vif-CUL5 complex, we performed double affinity purifications using cells co-transfected with Vif-2 \times Strep and either A3G- or CUL5-3 \times Flag (Fig. 1d, e). After purification first with Strep-Tactin and second with anti-Flag beads, mass spectrometry analysis of the final elution revealed the presence of CUL5, ELOB, ELOC, RBX2 and invariably CBF- β , strongly suggesting that this last protein may be a new component of the Vif E3 ubiquitin ligase complex (other factors from single Vif purifications depicted in Fig. 1c were not present). To confirm this interaction and the composition of the complex, we performed an additional double affinity purification experiment using

protein complex containing Vif, CBF- β and ELOBC binds to A3G but not the related Vif-resistant deaminase, A3A (Fig. 2c). These observations suggested that Vif, CBF- β and ELOBC form a subunit of the E3 complex for CUL5/RBX2 that enables specific interaction with A3G but not A3A proteins.

To test the activity of the reconstituted six protein complex, CUL5/ELOBC/Vif/CBF- β (CRL5-Vif-CBF- β), we assayed substrate polyubiquitination activities using two distinct and well characterized E2 ubiquitin-conjugating enzymes, UBE2R1 (hCDC34a) and UBE2A, which are capable of forming specific K48 and heterogenous linkages, respectively^{19,20}. With UBE2R1, CRL5-Vif-CBF- β was able to promote the formation of high-molecular mass K48 chains on A3G, but not A3A, supporting the chain linkage and substrate specificity of the reconstituted E3 complex. A3G also possessed autoubiquitination activity with UBE2R1, but not UBE2A, on substrate A3s (Supplementary Fig. 2). A3G was also ubiquitinated with NEDD8-modified CUL5, because NEDD8ylation is required for CUL5 to degrade A3G *in vivo* (Supplementary Fig. 3). Similarly, with UBCH5b, CRL5-Vif-CBF- β was able to promote the specific polyubiquitination of A3G and elicit Vif autoubiquitination activity (Supplementary Fig. 4). We conclude that the reconstituted Vif E3 ligase is specific for A3G,

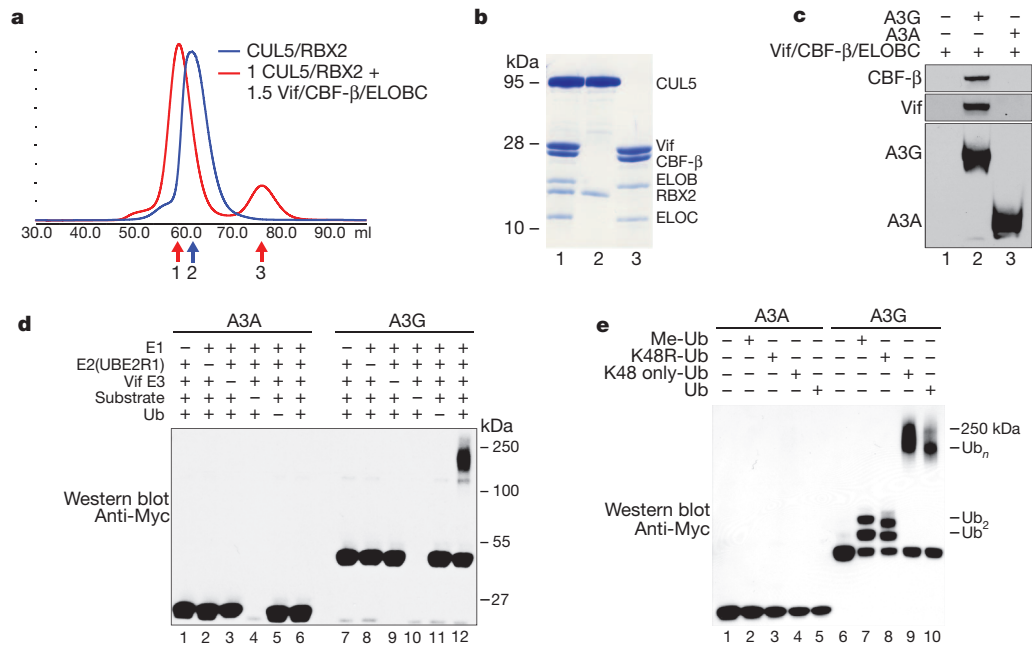

Figure 2 | CBF-β is a stoichiometric component of the Vif E3 ubiquitin ligase. **a**, Size exclusion chromatography of recombinant purified CUL5/RBX2 (blue) overlaid with CUL5/RBX2 mixed with 1.5 equivalents of purified Vif substrate adaptor containing Vif, ELOBC and CBF-β (red). **b**, Coomassie-stained SDS-PAGE of fractions labelled 1–3 in **a** indicating the Vif substrate adaptor and a six-protein assembly (CRL5–Vif–CBF-β) co-purify as stable monodisperse species. **c**, A3G, but not A3A, directly binds the tetrameric Vif substrate adaptor in pull-down experiments *in vitro*. **d**, CRL5–Vif–CBF-β is an E3 ligase that promotes polyubiquitination of A3G, but not A3A (detected

using an anti-c-Myc antibody to the C-terminal tag on the deaminases). Ub, ubiquitin. **e**, CRL5–Vif–CBF-β and UBE2R1 catalyse formation of K48-linked chains on A3G. Immunoblots showing substrate in ubiquitination reactions containing UBE2R1 as E2, no ubiquitin, Me-ubiquitin, K48R-ubiquitin, K48-only ubiquitin or wild-type ubiquitin. Reactions with Me-ubiquitin indicate that at least two distinct sites are modified on A3G; K48R recapitulates the pattern observed with Me-ubiquitin, whereas both wild type and K48R-only ubiquitin result in extensive polyubiquitin chains.

supports K48 chain formation and can function with at least two ubiquitin conjugating enzymes *in vitro*. It is conceivable that these two ubiquitin-conjugating enzymes work together in cells to promote multi-monoubiquitination of A3G followed by specific chain elongation, as described for other RING E3s^{24,25}, but additional work will be necessary to rule out other E2s *in vivo*.

To determine if CBF-β is required for Vif folding and/or stability in living cells, we transfected a constant amount of Vif into HEK293T cells expressing either a scrambled short hairpin (sh)RNA or a CBF-β-specific shRNA. The levels of steady-state Vif were threefold lower in CBF-β-depleted cells than in the scrambled control cells (Fig. 3a). Proteasome inhibitor MG132 reversed this effect, suggesting that Vif

Figure 3 | CBF-β and Vif collaborate to degrade APOBEC3G and enable HIV-1 infectivity. **a**, CBF-β-depleted HEK293T cells have lower steady-state Vif levels, which recover upon treatment with 2.5 μM MG132. **b**, Infectivity of replication-competent, Vif-proficient HIV-1 in the presence and absence of CBF-β and A3G ($n = 3$; mean, s.d.). Immunoblots are shown for the indicated proteins in virus-producing cells and viral particles. **c**, Infectivity of HIV-GFP produced using HEK293T-shCBF-β or HEK293T-shControl clones transfected with the single-cycle virus cocktail, A3G, Vif and CBF-β as

indicated ($n = 3$; mean, s.d.). The corresponding immunoblots are shown below. **d**, Infectivity of a Vif-deficient HIV-1 molecular clone produced in the presence or absence of human or rhesus A3G-HA, HIV or SIV Vif–Myc, and CBF-β as indicated ($n = 3$; mean, s.d.). Immunoblots are shown for the indicated proteins in virus-producing cells and viral particles with two exposures of the anti-Myc (Vif) blot shown to clarify the SIV Vif signal (the longer exposure also shows endogenous c-Myc).

Figure 4 | Model for Vif-CBF- β E3 ligase formation and APOBEC3G polyubiquitination and degradation. Vif is depicted hijacking cellular CBF- β to the E3 ubiquitin ligase complex required for A3G polyubiquitination and degradation. Vif may recruit newly translated CBF- β (not shown) and/or hijack existing CBF- β from RUNX transcription complexes.

degradation is accelerated without CBF- β . Analogous data were obtained when Vif was expressed from a proviral plasmid in CBF- β -depleted cells and complemented with a CBF- β expression plasmid (Supplementary Fig. 5).

Based on these observations, we predicted that CBF- β knockdown should result in less functional Vif and less infectious HIV-1 particles when produced in the presence of A3G. To test this prediction, shRNA was used to deplete CBF- β stably in HEK293T cells, and a knockdown clone was used to produce replication competent Vif-proficient HIV-1 in the presence or absence of A3G and CBF- β expressed from plasmids (Fig. 3b). In CBF- β depleted cells, steady-state Vif levels were very low despite equivalent levels of virus production as indicated by capsid. Moreover, Vif levels increased when CBF- β was replenished by complementation, and this correlated with decreases in cellular and viral A3G levels and corresponding increases in viral infectivity. In the absence of A3G, no difference in infectivity was observed regardless of cellular CBF- β or Vif levels. Titration experiments showed that CBF- β complementation is dose-responsive (Supplementary Fig. 6). Analogous results were obtained with a multi-vector HIV/green fluorescent protein (GFP) system (Fig. 3c and Supplementary Fig. 7). The Vif/CBF- β interaction was confirmed in virus-producing cells by co-immunoprecipitation experiments (Supplementary Fig. 8). Furthermore, SIVmac239 Vif requires CBF- β to degrade rhesus macaque A3G and promote viral infectivity (Fig. 3d). Interestingly, in contrast to HIV Vif, lower steady-state levels of SIV Vif were observed in the presence of CBF- β , which may be functionally significant or may be a consequence of the heterologous assay system (that is, expressing SIV/rhesus proteins in human cells). Nevertheless, these results demonstrate the essential and conserved nature of CBF- β for Vif function in promoting A3G degradation and efficient virus replication.

Our proteomic, biochemical and genetic studies combine to suggest a model in which HIV-1 Vif hijacks the cellular transcription factor CBF- β to facilitate Vif folding and/or stability as well as nucleation of the rest of the E3 ubiquitin ligase complex (Fig. 4). CBF- β is required for A3G substrate binding and, ultimately, for polyubiquitination and degradation, thereby enabling the production of infectious viral particles. Because genetic studies have shown that Vif is also capable of degrading APOBEC3F and several other human APOBEC3 proteins^{2,3,23} most of which are expressed in primary CD4+ T lymphocytes^{26,27}, it is quite likely that CBF- β is required for counteracting multiple endogenous APOBEC3s and thus for rendering T lymphocytes permissive for HIV-1 replication. We anticipate that the development of antiviral therapies that antagonize the CBF- β -Vif interaction will be more powerful than those that specifically target the A3G-Vif interaction, because they have the potential to unleash the simultaneous restriction potential of multiple APOBEC3s analogous to current combinatorial therapies.

METHODS SUMMARY

Affinity tagging, purification¹⁴ and ubiquitination assays²⁸ were performed as described. Recombinant A3A and A3G were purified as Myc-His tagged proteins from HEK293 cells. HIV-1 infectivity studies used an HIV-1_{IIIIB} proviral DNA construct (with or without Vif) or an HIV-GFP reporter plasmid set. Control (RHS4346) and CBF- β (RHS4430-99161432) shRNA constructs were obtained from Open Biosystems. A CBF- β complementary DNA matching NM_001755.2 was cloned from the CEM T cell line by RT-PCR. Immunoblots used antibodies to A3G (National Institutes of Health (NIH) ARRRP 10201 courtesy of J. Lingappa), CBF- β (Santa Cruz Biotechnology), HA (HA.11; Covance), TUB (tubulin; Covance), c-Myc (Sigma), Vif (NIH ARRRP 2221 courtesy of D. Gabuzda) and p24/capsid (NIH ARRRP 3537 courtesy of B. Chesebro and K. Wehrly). Details are provided in the Supplementary Methods.
